13. SUPPLEMENTARY NOTES

14. ABSTRACT

Biomedical literature represents the primary source of experimental data and biological knowledge. This project developed a text mining system for pathogens of biodefense relevance, focusing on mining pathogen-host proteomic data. We developed a Support Vector Machine (SVM)-based system to identify abstracts containing protein interaction information using an annotated corpus of 1360 MEDLINE abstracts as the training set. It achieved good performance on document classification with a precision of over 80% among top 50 ranked abstracts. The SVM-based method is further augmented with other text mining tools (such as PIE) for mining and tagging PPI information. As part of an effort in enabling text mining tools for realworld applications, we coupled our analysis with the functional annotation of proteomic experiment. All the data was then loaded into iProXpress system and provided to the collaborating USAMRIID laboratory for the analysis of bacterial pathogen proteomics data.

15. SUBJECT TERMS

Text mining, pathogenesis, pathogen-host protein-protein interaction, literature corpus, machine learning, support vector machine (SVM), proteomics data analysis

INTRODUCTION:

Due to the heightened concern about bioterrorism and emerging/reemerging infectious diseases, there are growing interests and pressing needs in speeding up the basic research as well as data mining of pathogenesis-related proteins in pathogens of military relevance, which may lead to better targets for disease diagnosis, prevention and therapy. This project specifically focused on pathogenesis-related protein data mining from scientific literature by developing an automated text mining system to f acilitate literature-based curation of such proteins (1 st year), and from proteomics and functional genom ics data through an integrated protein bioinform atics analysis system (2nd year, revised). We refer to the project as the **Pathogen Mining System**. The text mining system development primarily concerns the pathogen-host protein-protein interaction (PH-PPI) in formation from MEDLINE abstracts. The proteom ics and genom ics data mining concerns the analysis of proteomics data from *Burkholderia* under simulated growth condition, a project under the **Cooperative Research and Development Agreement with USAMRIID** (USAMRMC Control No: W81XWH-09-0003) [**Appendix I**].

BODY:

YEAR ONE

The primary objective of the first y ear of the p roject was to develop a text-m ining system to identify pathogenesis-related papers and extract information on pathogenicity and host-pathogen interactions. There were three tasks:

- Task1 (M01-03): Compilation of training and benchmarking literature corpus. Manual compilation of literature corpus as a posit ive training set of 300 pathogenesis -related papers with pathogen-host protein-protein interaction information.
- Task2 (M04-09): Development and evaluation of text-mining algorithms. Development of a text-mining system for document retrieval, entity recognition, and document categorization. Named-entity tagging tools as well as algorithmes for document classification and information extraction, including machine learning and rule -based methods evaluated.
- Task3 (M10-12): Development of web interface for automated literature mining. Development of web-based graphical user in terface for query submission and for literature mining result display with automatically tagged abstracts.

I. Literature data sets for machine learning algorithm training

Literature data sets (literature corpus) consisting of positive and negative data are necessary for training machine learning algorithms, such as Supporter Vector Machine (SVM), for text mining of pathogen esis-related pathogen and host proteins from literature. We focused on specific pathogen and host protein-protein interactions (PH-PPI). Unlike those for protein-protein interactions of the same species taking place within an organism, curated positive training data sets are rare for PH-PPI, especially for bacterial PH-PPI, and most such data are buried in the literature. Also because the bacterial PH-PPI in formation is much more difficult to distinguish from the same-species PPI than viral PH-PPI information would, we decided to separate training

set for the bacterial PH-PPI from that of viral PH-PPI, and to concentrate on the form er. Thus, we generated the literature training sets through manual curation of a set of ~2000 abstracts retrieved from PubMed based on query terms "bacterial pathogen and protein interaction".

- 1. Positive literature set of PH-PPIs. We compiled 300 abstracts (PMIDs) that are reviewed to contain PH-PPI, and the sentence s providing the evidence fo r such interactions are also tagg ed (highlighted). The sour ces f or deriving the set of lite rature also include prote in databases (UniProtKB and IntAct) where literature with protein interactions is cited for protein entries. Of the 300 abstracts, ~54% are for viral-host PPI, which are all derived from literature cited in databases; while ~46% are for bacterial-host PPI, most of which are from PubMed search. Because the primary interests of pathogens for the USAMRIID are on CDC catego ry A/B viral and bacterial pathogens, the abstracts for training have a balanced coverage of the bacterial and viral groups of organisms. In the training set, viral pathogens include Ebola, Lassa, HIV, HBV and bacterial pathogens include Yersinia pestis, Bacillus anthracis, Salmonella, and Shigella. In most cases the host is human, but may also include other mammal species.
- **2. Negative literature set of PH-PPIs.** Of the ~2000 abstracts retrieved from PubMed based on general keyword search "bacterial host protein interaction", ~1225 abstracts were more anually selected as negative ones, which may describe pathogen gene- or protein-related information but clearly lack of specific PH-PPI information.

The data sets for bacteria 1 PH-PPI are available at http://pir.georgetown.edu/staff/huz/tatrc/ (tatrc_dataset_positive.html and tatrc_dataset_negative.html), including 135 positive and 1225 negative abstracts. Evidence sentences in the positive abstracts were also annotated. The data set is currently for internal use and will eventually be made public for use in developing text mining algorithms by the text mining community.

II. Machine learning algorithm development for text mining of pathogenesis proteins

We developed and evaluated machine learningbased text-m ining m ethods for retrieving MEDLINE abstracts containing pathogen and host protein-protein interaction information based on the literature training set. We used a publicly available Support Vector Machine (SVM) package, S VM*light* (see http://svmlight.joachims.org/), to train the classifier, and tested and evaluated both abstract- and sentence-based classifiers to recognize PH-PPI-containing abstracts. Detailed methodology and results are described in a conference paper (Xuellet al., 2008) [Appendix II] and a journal article (Yin et al., 2009) [Appendix III].

1. Abstract-based algorithm. The training task can be at abstract level (ALT) to build a system to rank a set of abstracts. The abstracts in the dataset were preprocessed first by norm alizing the nouns, verbs, and adjectives, followed by extracting the unigrams and bigrams in both title and abstract to construct the sample features. The SVM was trained to class ify these 1360 abstracts (both positive and negative) by 10-fold cross-validation. Given a threshold value, abstracts with scoreshigher than the threshold from the classification was based on the total feature of the abstract. We tried different kernel functions in SVM in cluding linear function, polynomial, and RBF and found linear function was the best.

- 2. Sentence-based algorithm. The training task can also be at sentence level (SLT) to build a system to rank the abstracts. Individual sentences from abstracts were first extracted and labe led with corresponding PubMed ID (P MID) appended with a sequential number of the sentence in the given abstract. The sentences were then preprocessed similarly as above in the abstract-based algorithm. Untagged sentences from positive abstracts were not used for training but included in the test dataset only. The SVM was trained with linear function at the sentence-based, and 10-fold cross-validation was used to construct training and test dataset. Each sentence received a score from the classifier, and the highest sentence score would be assigned to the abstract as the final discriminating value. Similar to ALT method, a threshold value was set to assign positive or negative abstracts from the classifier, but the classification in SLT method was based on the feature of sentences.
- **3. Results and comparison between ALT and SLT methods.** The testing results of the trained SVM were evaluated us ing the ROC curve d epicting the relationship betw een the true positive (TP) and f alse positive (FP) rates (**Figure 1**). In the high specificity area (specificity=1 -FP,

towards the left of the ROC curve), given the sam e sensitivity (TP), the sentencebased method gave higher specificity (redline) than the abs tract-based (b lue-line); while in the high sensitiv ity area (sensitivity=TP, towards the top of the ROC curve), the two methods seemed to have little difference. For exam ple, the top 200scored abstracts from the classifier using sentence-based method contained 61% true positive abs tracts, com pared to 53 % with abstract-based method. The results suggest g m ethod that the sentence-based trainin tends to have better perform ance than the abstract-based m ethod for r etrieving pathogen host PPI abstracts. We also extended the SVM train ing to feature selection to enhance its performance.

Figure 1. Receiver operating characteristics curve (ROC) analysis of ALT (blue) and SLT (red).

4. Feature selection method and information gain. We investigated the inclusion of a feature selection method (i.e., inform ation gain) into the machine leaning system. We compared *no feature selection* method with *Information Gain* feature selection on both abstract and sentence levels. We found that *Information Gain* reduced the dimension of Vector Space and could improve the performance of the SVM than *no feature selection*. Moreover, the results showed that the sen tence-level SVM (training based on highlighted sentences) had better performance and greater prospect than the abstract-based method.

III. Evaluation of existing text mining tools on the PH-PPI data sets

While developing and evaluating the SVM-based text mining system for PH-PPI during the first year of the project, we are also exploring the existing text mining tools that can be useful for text

mining of PH-PPI inform ation. The se public text mining tools include PIE (Kim et al., 2008), iHOP (Fernández et al., 2007), and others as included in MetaServer (Leitner et al., 2008), which is a central sever integrating text m ining tool s particip ating in the BioCreative Challenge Evaluation for m olecular (gene and protein) data from literature (Hirschman et al., 2005). Protein-protein interaction text mining has been a major task in the 2nd BioCreative Challenge Evaluation (Wilbur et al., 2007).

We evaluated the PPI text m ining tool PIE (Protein I nteraction inf ormation Extraction, http://pie.snu.ac.kr/index.php) using the curated positive data set for bacterial as well as the viral PH-PPI. PIE highlights sentences in abstracts that contain protein interaction information, in which the detected words/phrases for the interacting proteins and the interaction relations are also distinguished. **Table 1** (bacterial set) and **Table 2** (viral set) summarize the comparison of the PIE PPI extraction with the manual annotated abstracts and sentences.

Table 1. Comparison of PIE text mining of PPI to the manual bacterial data set

		# Abstracts	% Data set
	Manually-tagged bacteria data set	135	100%
Abstract	Positive abstracts tagged by PIE	110	81.5%
level	Positive abstracts not tagged by PIE	25	18.5%
	Abstracts with >=1 manually-identified sentence tagged by PIE	70	51.9%
	Abstracts with no manually-identified sentence tagged by PIE	65	48.1%
	Manually-tagged (positive) sentences in data set	247	100%
	Positive sentences tagged by PIE	98	39.7%
Sentence	Positive sentences missed by PIE	149	60.3%
level	Sentences tagged by PIE in data set	298	100%
	Positive sentences tagged by PIE	98	32.9%
	Negative sentences tagged by PIE	200	67.1%

Table 2. Comparison of PIE text mining of PPI to the manual viral data set

		# Abstracts	% Data set
	Manually-tagged virus data set	170	100%
Abstract	Abstract Positive abstracts tagged by PIE		95.9%
level	Positive abstracts not tagged by PIE	7	4.1%
	Abstracts with >=1 manually-identified sentence tagged by PIE	145	85.3%
	Abstracts with no manually-identified sentence tagged by PIE	25	14.7%
Sentence	Manually-tagged sentences (positive) in the data set	279	100%
level	Positive sentences tagged by PIE	205	73.5%
15 / 61	Positive sentences missed by PIE	74	26.5%

The results show that PIE recognizes ~82% of the manually tagged abstracts and ~40% manually tagged sentences for the bacterial data set, and recognizes ~96% manually tagged abstracts and 74% manually tagged sentences for the vira 1 data set. While we need to compare the PIE's performance with other similar tools on the same data set, the relatively high recognition of

positive abstracts by P IE is a d esired feature for retrieving the PH-PPI containing abstracts to facilitate the manual curation efforts. Therefore the PIE tool can augm ent the pathogen m ining system for this project. The detailed evaluation results of the PIE tool are a vailable at: http://pir.georgetown.edu/staff/huz/tatrc/dataset/ with the bacterial set (PIE_evaluation_bacterial _positive.mht).

IV. iProLINK framework to link text mining to ontology and systems biology

Another ongoing effort relevant to the project on the PH-PPI text mining is the iProLINK framework development, an effort in bringing together text mining, biological ontology and systems biology communities to develop text mining tools that can be broadly utilized by the biology communities for real-world applications.

The ever-increasing scientific literature and the exponential growth of large-scale molecular data have prompted active research in biological text mining to facilitate literature-based curation of molecular databases. Meanwhile, system s biology and bio-ontologies are emerging as critical tools in biological research wher e complex data in disparate resources are generated, integrated and analyzed. Both rely on literature for data a nnotation and analysis. The challen ges facing us are to develop broadly utilized text mining tools and system s that need to involve bot h developers and users for system development and evaluation. iP roLINK, extending from a previously developed text mining resource (H u et al., 2004), is designed as a fram ework for linking text mining tools with ontology and system s biology. The fram ework focuses on text mining of protein-protein interaction, including the protein posttranslational modification such as phosphorylation, which can be applied to curation of molecular and ontological data and analysis of systems biology data.

The framework consists of two m ajor components: a user interface for text m ining of PPI from an integrated tool server and software m odules to allow text m ining outputs to be created, ranked, and used by the community. Use cases are presented for assessing the gaps and m aking recommendations for future developm ent. The detailed components and case studies are described in a conference paper (Hu et al., 2008) [Appendix IV]. The iProLINK framework will benefit the Pathogen Mining project by not only maximally utilizing the different tools developed by the text mining community and providing an interface for community access, but also encouraging the use and application of these tools in the real-world applications such as assisting genomic and proteomic data analysis and pathogen data mining. We further organized a workshop during the P AG XVII (Plant and Animal Genome Conference) on "Text Mining for Database Curation" (Wu, 2009) (http://www.intl-pag.org/17/17-pir.html) [Appendix V] to present the iProLINK fram ework and to foster discussion on the development of text mining systems that address the needs of the biocuration and biological research community.

YEAR TWO

The objective of the second year was to use the Pathogen Mining System (**Figure 2**) to sem i-automatically m ine text for inform ation on pathogenesis-related proteins, including host interacting proteins, and to use the text m ining results in c omprehensive functional analysis of high-throughput proteomic data from pathogenic and non-pathogenic *Burkholderia* strains grown

in different kinds of media. The scope of the project was defined under the Cooperative Research and Developm ent Agreem ent with USAMRIID entitled " *Reanalysis and Functional Interpretation of Proteomics Data from Bacterial Cells under Simulated Growth Condition*," which focused on prior 2DGE-MS (2D gel electrophoresis-mass spectrometry) proteomics data from *Burkholderia* strains.

- Task1 (M13-15): Preliminary analysis of the Burkholderia proteomic space. Collecting data on Burkholderia strains and developing the scope of computational work performed to analyze Burkholderia proteomic data.
- Task2 (M16-18): Protein identification using MASCOT. Initial protein identification using MASCOT, and c onfirmation of the id entification through m anual checking and mapping of IDs back to 2-D gels.
- Task3 (M18-24): Annotation of identified proteins and integration data into iProXpress. Manual annotation of proteins identified using RACE-P interface, automated annotation of the Burkholderia genome using RAST, lite rature mining of patho genic Burkholderia proteins, and using iProXpress to perform mining and analysis of the data.

Figure 2. Pathogen Mining System.

I. Collaboration with USAMRIID research groups

The second year of the Pathogen Mining project was revised to fo cus on the collaborative work with the USAMRIID on bacterial pathogen proteomics data analysis using the iProXpress system developed at PIR (Huang et al., 2007). In the beginning of the project, we met with the USAMRIID research groups and disc ussed the research activities in their labs complimentary to this project. We agreed to analyze *Burkholderia* proteomic data obtained from growing strains *in vitro* and m edia mimicking *in vivo* conditions using lite rature m ining and data mining methodologies that have been already develope d at PIR. The hypothesis for the original proteomic experiments is as follows: Proteins important to Glanders disease pathology m ay be discovered through the comparative analysis of proteomes derived from bacteria cultured *in vitro* under conditions that partially simulate *in vivo* growth in the mammalian host.

To test this hypothesis *Burkholderia mallei* (human pathogen), *B. pseudomallei* (human pathogen), *B. vietnamiensis* (opportunistic human pathogen) and *B. thailandensis* (avirulent) were grown *in vitro* and simulated *in vivo* conditions (iron and calcium limited media) and their protein component was analyzed using 2-D gels. Proteins that were up-regulated and down-regulated were excised from the gels and was analyzed using MALDI-TOF-MS and peak lists were obtained. These peak lists were initially analyzed five years back against two *Burkholderia* proteomes. With the advent of twenty additional *Burkholderia* proteomes in the databases, we reanalyzed the peak list for better identification of the proteins. Then perform detailed analysis of the proteins. The objective of this collaboration was to use the integrated proteomics analysis system, iProXpress, coupled with the TATRC-funded project, Pathogen Mining System, to facilitate the re-evaluation and functional interpretation and hypothesis for mulation from the legacy data.

1. Protein identification using MASCOT. The initial step towards protein identification is mapping the experim ental organisms to specific *Burkholderia* strains in the NCBI taxonomy database (**Table 3**).

Table3. Mapping of strains used in experiment to NCBI taxonomy IDs
Each experiment was conducted with induced vs. uninduced growth condition of the organism.

Experiment/	Treatments	Strains Used	Mapped to NCBI taxonomy ID
Gel	(Uninduced/Induced)		
1	1/7	B. mallei GB8	B. mallei ATCC 23344 (taxid 243160)
2	2/8	B. mallei GB6	B. mallei (taxid 13373)
3	3/9	B. mallei GB5	B. mallei NCTC 10229 (taxid 412022)
4	4/10	B. pseudomallei 1126B	B. pseudomallei (taxid 320373)
5	5/11	B. thailandensis E254	B. thailandensis (taxid 271848)
6	6/12	B. vietnamensis FCO369	B. vietnamensis (taxid 269482)

We used M ascot Peptide Mass Fing erprint to identify proteins us ing the data files provided by Dr. Powell of US AMRIID. Dr. Powell, with cl ose collaboration with us, confirm ed the experimental conditions and the strains of *Burkholderia* (**Table 4**) for 200 MALDI spectra and they were used for Protein Identification with MASCOT search engine from the Proteomics Lab at the University of Delaware.

Table 4. List of *Burkholderia* Strains.

Organism Name	Taxonomy ID	# of files	# of Sequences
Burkholderia mallei (Pseudomonas mallei)	13373 77		4831
Burkholderia vietnamiensis (strain G4 / LMG	269482 35		7410
22486) (Burkholderia cepacia (strain R1808))			
Burkholderia thailandensis (strain E264/ATCC	271848 38		5563
700388 / DSM 13276 / CIP 106301)			
Burkholderia pseudomallei (strain 668)	320373 26		7215
Burkholderia mallei (strain NCTC 10229)	412022 24		5309

Each spectrum is searched against its corresponding sequence databases using **Mascot Peptide Mass Fingerprint.** Search engine used is Mascot versi on 2.2, the inform ation associated with Mascot Peptide Mass Fingerprint search is listed as follows:

Search Parameters:

Type of search: Peptide Mass Fingerprint

Enzyme: Trypsin

Fixed modifications: Carbamidomethyl (C) Variable modifications: Oxidation (M)

Mass values: Monoisotopic Protein Mass: Unrestricted

Peptide Mass Tolerance: ± 1.2 Da

Peptide Charge State: 1+ Max Missed Cleavages: 1

Protein score is -10*Log(P), where P is the probability that the observed match is a random event. For each spectra, we recorded all the identified proteins which are significant (p<0.05), not just top scoring protein. Over all, we reanalyzed the data using MASCOT, finished the final identification, functional annotation of the proteins and mapping them to the 2-D gel spots, and identified 173 unique UniProtKB IDs (W81XWH-07-2-0112_Supplement.xls) [Appendix VI].

2. Manual Annotation of Identified Proteins in RACE-P interface. Of the proteins identified, 31 are UniProtKB/Swiss-Prot entries and have already been manually curated. The next step was to annotate the other proteins . Rapid Annotation interface fo r proteins (RACE-P) a web interface developed at PIR was used to annotate these proteins. The features of the RACE-P page are divided into following blocks:

BLOCK 1: Protein Name.

The name of the protein, short nam e, EC Number and synonyms are derived from publications and/or closely related U niProtKB/Swiss-Prot homolog. In twenty -one cases, no publications or closely related UniProtKB/Swiss-Prot homolog of the protein c ould be found; hence the nam e was derived from the author submitted data in the corresponding UniProtKB/TrEMBL entry.

BLOCK 2: Gene Name.

The Gene Na me, synonym and Gene ID are de rived from the publications, model organism database and/or the author submitted data in UniProtKB/TrEMBL. This block also contains a link to the gene record in Organism Database, www.burkholderia.com.

BLOCK 3: Bibliography.

This block contains inform ation on the protein from Publications. Publications which describe experiments performed on the gene or protein are included in this section. Review articles are usually excluded.

BLOCK 4: Gene Ontology.

The Gene Ontology terms included in this section are derived only from publications.

BLOCK 5: Computational Analysis.

This is done to confirm and/or add new inform ation. The tools used are European Molecular Biology Open Software Suite (EMBOSS) and PIR developed tools.

BLOCK 6: Protein family.

Families are created consisting of 50 BLAST hits with a t least 70 % end-to-end overlap to the query and e-value better than 1.0E-10. The family names, synonym and EC Numbers are derived from the UniProtKB/SwissProt entresis in the family. There were instances where no UniProtKB/SwissProt protein fit the family criteria.

A total of 66 proteins are a nnotated in the RACE-P, 24 of which have closely related UniProtKB/Swiss-Prot entries and 42 proteins do not. The remaining 76 are uncharacterized hypothetical proteins. An Excel file (W 81XWH-07-2-0112_Supplement.xls) was created with the following column. **Table 5** shows the manual annotation of identified *Burkholderia* proteins, displaying partial sections of the annotated file.

Spectrum – The spectrum file name of the spot

Accession – UniProtKB ID mapped to the spot

Protein Name— Name given in the RACE-P annotation or UniProtKB/Swiss-Prot name

Mascot Protein – UniProtKB Accession, UniProt KB Protein Name and organism

Score, Threshold, Expect, PeptideMatched – Numerical results from mascot

Organism used in experiment – Organism name in Dr Powell's original file

Identified Strains – *Burkholderia* strains in the NCBI taxonomy database mapped to the TaxID

TaxID – Taxonomy ID

Un/Induced – Experimental condition; Induced/Uninduced

Sample – Gel Number

Spot Number – Spot on the gel

Comp. – Experimental comparison file name

Comp description – Experimental observation from comparisons between gels

OLD TIGR – Original TIGR annotation

Possible Associations searching by spot - Comments from Dr. Powell

Comments – Comments from Dr. Powel

3. Large-scale Annotation of the Five Burkholderia genomes using RAST. In addition the manual annotation of the proteins, we perfor med large-scale automated annotation using Rapid Annotation using Subsystem Technology (RAST) server. RAST is an autom ated service provided by one of PIR collaborat ors and it is useful in annot ating bacterial and archaeal genomes (Aziz et al., 2008). We ran the 5 *Burkholderia* genome used in the 2-D gel experiments. The input into the web based program is the genome e sequence in GenBank for mat. **Figure 3** represents the output for *Burkholderia mallei* ATCC 23344. The image provides an overview of

W81XWH-07-2-0112 Page 12

the genome and classifies the proteins into subsystems. The subsystem classification is different for the five genomes: for instance, *B. mallei* ATCC 23344 has 125 protein involved in virulence, while *B. vietnamiensis* has 204. The RAST result also provides additional annotation of the proteins identified.

Table 5. Manual annotation of identified *Burkholderia* proteins Showing only partial sections of the annotated file (W81XWH-07-2-0112_Supplement.xls)

Spectrum	Accession	Protein Name	Identified Strains	Un/Induced	Sample	Spot Number
8.206_44_0001	Q62GL8	30S ribosomal protein S14	B. mallei ATCC 23344	Induced 8B		206
Usamrid66_0001	A3NEG6	30S ribosomal protein S14	B. pseudomallei 668	Uninduced 4C		144
8.161_52_0001	Q62GL1	30S ribosomal protein S3	B. mallei ATCC 23344	Induced 8B		161
Usamrid92_0001	A4JAP6	30S ribosomal protein S3	B. vietnamiensis G4	Uninduced 6B

4. Literature mining for *Burkholdria* **Pathogenicity.** Less than 4000 articles were retrieved from PubMed using the keyword search "Burkholderia". We could not find publications on most of the thirty-two UniProtKB/TrEMBL proteins indentified in the previous quarter. Though we could not get m uch inform ation based on our dataset, useful infor mation on *Burkholderia* parthenogenesis can be derived from publicat ions in PubMed. The literature m ining tool developed in the first year of th is project is used to s earch for sc ientific a rticles that show

Pathogen-Host Protein-Protein Interaction (Guixian *et al.*, 2008). Of the 3712 articles searched, 34 research articles are recognized as positive. 16 were m anually determined to be true positive for Pathogen-Host Protein-Protein Interaction. Most of the othe r articles describe pathogenic proteins and complexes without the host proteins they interact with.

Figure 3. RAST results for *Burkholderia mallei* ATCC 23344.

5. Integration of proteins identified into iProXpress. *i*ProXpress (integrated Protein eXpression) is an integrated protein expres sion analysis system (Huang et al., 2007). 141 proteins identified by MA SCOT with p-value <= 0.05 have been uploaded into *i*ProXpress (**Figure 4**). *i*ProXpress lists all entries and they are grouped by Spectrum. The data can be analyzed in the web in terface. Functions of the system include Functional Profiling (sample in **Figure 5**), Protein Inform ation Matrix and ID mapping. The information is accessible from http://pir.georgetown.edu/iproxpress/, under "Other data sets". The web pages are password protected and is provided to Dr. Powell for visualization of the annotated dataset.

KEY RESEARCH ACCOMPLISHMENTS:

- We manually curated p athogen-host PPI literature data sets that are n ecessary for the machine learning m ethod as well as beneficial to the text m ining community when becoming publicly available.
- We developed and evaluated the S VM methods for classifying the abstracts with PH-PPI information, whose overall perform ance is best when using sentence level training and feature selection.
- We identified and evaluated existing public text mining tools such as PIE that can be augmenting the Pathogen Mining System.
- We initiated a comm unity collaborative effort under the iPr oLINK framework, which will be of great benefit to the Pathogen Mining System.
- We established close collaborations with U SAMRIID research groups to analyze pathogen genomic and proteomic data that will take advantage of the PH-PPI text mining.
- We identified proteins from prior 2DGE-MS Burkholderia proteomics data.
- We manually annotated the proteins in the RACE-P interface of iProClass.
- We integrated the identified proteins into iProXpress to perform mining and analysis of the data.

REPORTABLE OUTCOMES:

- 1. Cooperative Research and Development Agreement between Georgetown University and USAMRIID
- 2. Three research papers were generated from the project, reporting the SVM-based PH-PPI text m ining system (Xu et al., 2008; Yin et al., 2009) and an integrated text m ining framework for text mining and biology communities (Hu et al., 2008).
- 3. A workshop presentation at the 2009 PAG XV II (Plant and Animal Genome Conference) on the iProLINK framework (Wu, 2009) (http://www.intl-pag.org/17/17-pir.html).

CONCLUSIONS:

Biomedical literature represents the prim ary source of experim ental data, and developing text mining systems for mining such data for pathogens of biodefense relevance is the main objective for the first year of the projec t. We focus on text m ining of the host-pathogen protein-protein interactions. We developed an SVM-based automated system to identify MEDLINE abstracts containing HP-PPI inform ation. We observed that feature selection was effective not only in reducing the dim ensionality of features to build a compact system , but also in im proving document classification perform ance. We also observed abstract-level system s and sentencelevel system's yielded different classification of MEDLIN E abstracts, and the combination of these system's could improve the overall docum ent classification. To augm ent the SVM-base d PH-PPI mining methods, we also explored the public text mining tools for the PH-PPI m ining. We performed prelim inary evaluation on the P PI extraction tool P IE, and the results showed encouraging perform ance at least at the abstract level, suggesting that PIE can be potentially integrated into the Pathogen Mining System for improving the overall text mining capabilities of the system. Exploring public text mining tools is also part of the initia tive by PIR in order to develop a basic framework to bring together the text mining and biological communities to better develop text m ining tools for re al-world applications. Our s econd year tasks focused on the identification, annotation and analysis of and pr oteomic data for pathogens of biodefense and military relevance.

A COOPERATIVE RESEARCH AND DEVELOPMENT AGREEMENT

Between

Georgetown University 37th and O Streets, NW Washington, District of Columbia 20057 (Cooperator) and

U.S. Army Medical Research Institute of Infectious Diseases Fort Detrick, Maryland 21702-5011 (Laboratory)

Article 1. Background

- 1.00 This Agreement is entered into under the authority of the Federal Technology Transfer Act of 1986, 15 U.S.C. 3710a, et seq., between the Cooperator and the Laboratory, the parties to this Agreement.
- 1.01 Laboratory, on behalf of the U.S. Government, and Cooperator desire to cooperate in research and development on <u>Reanalysis and Functional Interpretation of Proteomics Data from Bacterial Cells under Simulated Growth Condition</u> according to the attached Statement of Work (SOW) described in Appendix A. NOW, THEREFORE, the parties agree as follows:

Article 2. Definitions

- 2.00 The following terms are defined for this Agreement as follows:
- 2.01 "Agreement" means this cooperative research and development agreement.
- 2.02 "Invention" and "Made" have the meanings set forth in Title 15 U.S.C. Section 3703(9) and (10).
- 2.03 "Proprietary Information" means information marked with a proprietary legend which embodies trade secrets developed at private expense or which is confidential business or financial information, provided that such information:
- (i) is not generally known, or which becomes generally known or available during the period of this Agreement from other sources without obligations concerning their confidentiality:
- (ii) has not been made available by the owners to others without obligation concerning its confidentiality; and

- (iii) is not already available to the receiving party without obligation concerning its confidentiality.
- (iv) is not independently developed by or on behalf of the receiving party, without reliance on the information received hereunder.
- 2.04 "Subject Data" means all recorded information first produced in the performance of this Agreement.
- 2.05 "Subject Invention" means any Invention Made as a consequence of, or in relation to, the performance of work under this Agreement.

Article 3. Research Scope and Administration

- 3.00 Statement of Work. Research performed under this Agreement shall be performed in accordance with the SOW incorporated as a part of this Agreement at Appendix A. It is agreed that any descriptions, statements, or specifications in the SOW shall be interpreted as goals and objectives of the services to be provided under this Agreement and not requirements or warranties. Laboratory and Cooperator will endeavor to achieve the goals and objectives of such services; however, each party acknowledges that such goals and objectives, or any anticipated schedule of performance, may not be achieved.
- 3.01 Review of Work. Periodic conferences shall be held between the parties for the purpose of reviewing the progress of work. It is understood that the nature of this research is such that completion within the period of performance specified, or within the limits of financial support allocated, cannot be guaranteed. Accordingly, all research will be performed in good faith.
- 3.02 Principal Investigator. Any work required by the Laboratory under the SOW will be performed under the supervision of Dr. Bradford Powell, U.S. Army Medical Research Institute of Infectious Diseases (USAMRIID) 1425 Porter Street, Fort Detrick, MD 21702-5011, Phone: 301-619-4933, Fax 301-619-2152 and Email: bradford.powell@amedd.army.mil, who, as co-principal investigator has responsibility for the scientific and technical conduct of this project on behalf of the Laboratory. Any work required by the Cooperator under the SOW will be performed under the supervision of Dr. Cathy H. Wu, Georgetown University Medical Center, 3300 Whitehaven Street, NW, Suite 1200, Washington, DC 20007, Phone: 202-687-1039, Fax: 202-687-0057, and Email: wuc@georgetown.edu, who, as co-principal investigator has responsibility for the scientific and technical conduct of this project on behalf of the Cooperator.
- 3.03 Collaboration <u>Changes</u>. If at any time the co-principal investigators determine that the research data dictates a substantial change in the direction of

the work, the parties shall make a good faith effort to agree on any necessary change to the SOW and make the change by written notice to the addresses listed in section 12.05 <u>Notices</u>.

3.04 <u>Final Report</u>. The parties shall prepare a final report of the results of this project within six months after completing the SOW.

Article 4. Ownership and Use of Physical Property

- 4.01 Ownership of Materials or Equipment. All materials or equipment developed or acquired under this Agreement by the parties shall be the property of the party which developed or acquired the property, except that government equipment provided by Laboratory (1) which through mixed funding or mixed development must be integrated into a larger system, or (2) which through normal use at the termination of the Agreement has a salvage value that is less than the return shipping costs, shall become the property of Cooperator.
- 4.02 <u>Use of Provided Materials</u>. Both parties agree that any materials relating to them which were provided by one party to the other party will be used for research purposes only. The materials shall not be sold, offered for sale, used for commercial purposes, or be furnished to any other party without advance written approval from the Provider's official signing this Agreement or from another official to whom the authority has been delegated, and any use or furnishing of material shall be subject to the restrictions and obligations imposed by this Agreement.

Article 5. Patent Rights

- 5.00 Reporting. The parties shall promptly report to each other all Subject Inventions reported to either party by its employees. All Subject Inventions Made during the performance of this Agreement shall be listed in the Final Report required by this Agreement.
- 5.01 Cooperator Employee Inventions. Laboratory waives any ownership rights the U.S. Government may have in Subject Inventions Made by Cooperator employees and agrees that Cooperator shall have the option to retain title in Subject Inventions Made by Cooperator employees. Cooperator shall notify Laboratory promptly upon making this election and agrees to timely file patent applications on Cooperator's Subject Invention at its own expense. Cooperator agrees to grant to the U.S. Government on Cooperator's Subject Inventions a nonexclusive, nontransferable, irrevocable, paid-up license in the patents covering a Subject Invention, to practice or have practiced, throughout the world by, or on behalf of the U.S. Government. The nonexclusive license shall be evidenced by a confirmatory license agreement prepared by Cooperator in a form satisfactory to Laboratory.

- 5.02 <u>Laboratory Employee Inventions</u>. Laboratory shall have the initial option to retain title to, and file patent application on, each Subject Invention Made by its employees. The Laboratory agrees to grant an exclusive license to any invention arising under this Agreement to which it has ownership to the Cooperator in accordance with Title 15 U.S. Code Section 3710a, on terms negotiated in good faith. Any invention arising under this Agreement is subject to the retention by the U.S. Government of nonexclusive, nontransferable, irrevocable, paid-up license to practice, or have practiced, the invention throughout the world by or on behalf of the U.S. Government.
- 5.03 <u>Joint Inventions</u>. Any Subject Invention patentable under U.S. patent law which is Made jointly by Laboratory employees and Cooperator employees under the Scope of Work of this Agreement shall be jointly owned by the parties. The parties shall discuss together a filing strategy and filing expenses related to the filing of the patent covering the Subject Invention. If a party decides not to retain its ownership rights to a jointly owned Subject Invention, it shall offer to assign such rights to the other party, pursuant to Paragraph 5.05, below.
- 5.04 Government Contractor Inventions. In accordance with 37 Code of Federal Regulations 401.14, if one of Laboratory's Contractors conceives an invention while performing services at Laboratory to fulfill Laboratory's obligations under this Agreement, Laboratory may require the Contractor to negotiate a separate agreement with Cooperator regarding allocation of rights to any Subject Invention the Contractor makes, solely or jointly, under this Agreement. The separate agreement (i.e., between the Cooperator and the Contractor) shall be negotiated prior to the Contractor undertaking work under this Agreement or, with the Laboratory's permission, upon the identification of a Subject Invention. In the absence of such a separate agreement, the Contractor agrees to grant the Cooperator an option for a license in Contractor's inventions of the same scope and terms set forth in this Agreement for inventions made by Laboratory employees.
- 5.05 Filing of Patent Applications. The party having the right to retain title to, and file patent applications on, a specific Subject Invention may elect not to file patent applications, provided it so advises the other party within 90 days from the date it reports the Subject Invention to the other party. Thereafter, the other party may elect to file patent applications on the Subject Invention and the party initially reporting the Subject Invention agrees to assign its ownership interest in the Subject Invention to the other party.
- 5.06 <u>Patent Expenses</u>. The expenses attendant to the filing of patent applications shall be borne by the party filing the patent application. Each party shall provide the other party with copies of the patent applications it files on any Subject Invention, along with the power to inspect and make copies of all documents retained in the official patent application files by the applicable patent

office. The parties agree to reasonably cooperate with each other in the preparation and filing of patent applications resulting from this Agreement.

Article 6. Exclusive License

- 6.00 <u>Grant</u>. The Laboratory agrees to grant to the Cooperator an exclusive license in each U.S. patent application, and patents issued thereon, covering a Subject Invention, which is filed by the Laboratory subject to the reservation of a nonexclusive, nontransferable, irrevocable, paid-up license to practice and have practiced the Subject Invention on behalf of the United States.
- 6.01 Exclusive License Terms. The Cooperator shall elect or decline to exercise its right to acquire an exclusive license to any Subject Invention within six months of being informed by the Laboratory of the Subject Invention. The specific royalty rate and other terms of license shall be negotiated promptly in good faith and in conformance with the laws of the United States.

Article 7. Background Patent(s)

- 7.00 <u>Laboratory Background Patent(s)</u>: Laboratory has filed patent application(s), or is the assignee of issued patent(s) which contain(s) claims that are related to research contemplated under this Agreement. No license(s) to this/these patent applications or issue patents is/are granted under this Agreement, and this/these application(s) and any continuations to it/them are specifically excluded from the definitions of "Subject Invention" contained in this Agreement.
- 7.01 Cooperator Background Patent(s): Cooperator has filed patent application(s), or is the assignee of issued patent(s) which contain(s) claims that are related to research contemplated under this Agreement. No license(s) to this/these patent applications or issue patents is/are granted under this Agreement, and this/these application(s) and any continuations to it/them are specifically excluded from the definitions of "Subject Invention" contained in this Agreement.

Article 8. Subject Data and Proprietary Information

- 8.00 <u>Subject Data Ownership</u>. Subject Data shall be jointly owned by the parties. Each party, upon request to the other party, shall have the right to review and to request delivery of all Subject Data, and delivery shall be made to the requesting party within two weeks of the request, except to the extent that such Subject Data are subject to a claim of confidentiality or privilege by a third party.
- 8.01 <u>Proprietary Information/Confidential Information</u>. Each party shall place a proprietary notice on all information it delivers to the other party under

this Agreement that it asserts is proprietary. The parties agree that any Proprietary Information or Confidential Information furnished by one party to the other party under this Agreement, or in contemplation of this Agreement, shall be used, reproduced and disclosed by the receiving party only for the purpose of carrying out this Agreement, and shall not be released by the receiving party to third parties unless consent to such release is obtained from the providing party.

- 8.02 <u>Army limited-access database</u>. Notwithstanding anything to the contrary in this Article, the existence of established CRADAs specifying areas of research and their total dollar amounts may be documented on limited access, password-protected websites of the U.S. Army Medical Research and Materiel Command (the parent organization of Laboratory), to provide the Command's leadership with a complete picture of military research efforts.
- 8.03 <u>Laboratory Contractors</u>. Cooperator acknowledges and agrees to allow Laboratory's disclosure of Cooperator's proprietary information to Laboratory's Contractors for the purposes of carrying out this Agreement. Laboratory agrees that it has or will ensure that its Contractors are under written obligation not to disclose Cooperator's proprietary information, except as required by law or court order, before Contractor employees have access to Cooperator's proprietary information under this Agreement.
- 8.04 Release Restrictions. Laboratory shall have the right to use all Subject Data for any Governmental purpose, but shall not release Subject Data publicly except: (i) Laboratory in reporting on the results of research may publish Subject Data in technical articles and other documents to the extent it determines to be appropriate; and (ii) Laboratory may release Subject Data where release is required by law or court order. The parties agree to confer prior to the publication of Subject Data to assure that no Proprietary Information is released and that patent rights are not jeopardized. Prior to submitting a manuscript for review which contains the results of the research under this Agreement, or prior to publication if no such review is made, each party shall be offered an ample opportunity to review any proposed manuscript and to file patent applications in a timely manner.
- 8.05 <u>FDA Documents</u>. If this Agreement involves a product regulated by the U.S. Food and Drug Administration (FDA), then the Cooperator or the U.S. Army Medical Research and Materiel Command, as appropriate, may file any required documentation with the FDA. In addition, the parties authorize and consent to allow each other or their contractors or agents access to, or to cross-reference, any documents filed with the FDA related to the product.

Article 9. Termination

- 9.00 <u>Termination by Mutual Consent</u>. Cooperator and Laboratory may elect to terminate this Agreement, or portions thereof, at any time by mutual consent.
- 9.01 <u>Termination by Unilateral Action</u>. Either party may unilaterally terminate this entire Agreement at any time by giving the other party written notice, not less than 30 days prior to the desired termination date.
- 9.02 <u>Termination Procedures</u>. In the event of termination, the parties shall specify the disposition of all property, patents and other results of work accomplished or in progress, arising from or performed under this Agreement by written notice. Upon receipt of a written termination notice, the parties shall not make any new commitments and shall, to the extent feasible, cancel all outstanding commitments that relate to this Agreement. Notwithstanding any other provision of this Agreement, any exclusive license entered into by the parties relating to this Agreement shall be simultaneously terminated unless the parties agree to retain such exclusive license.

Article 10. Disputes

10.00 <u>Settlement</u>. Any dispute arising under this Agreement which is not disposed of by agreement of the principal investigators shall be submitted jointly to the signatories of this Agreement. A joint decision of the signatories or their designees shall be the disposition of such dispute. However, nothing in this section shall prevent any party from pursuing any and all administrative and/or judicial remedies which may be allowable.

Article 11. Liability

- 11.00 <u>Property</u>. Neither party shall be responsible for damages to any property provided to, or acquired by, the other party pursuant to this Agreement.
- 11.01 No Warranty. The parties make no express or implied warranty as to any matter whatsoever, including the conditions of the research or any Invention or product, whether tangible or intangible, Made, or developed under this agreement, or the ownership, merchantability, or fitness for a particular purpose of the research or any Invention or product. The parties further make no warranty that the use of any invention or other intellectual property or product contributed, made or developed under this Agreement will not infringe any other United States or foreign patent or other intellectual property right. In no event will any party be liable to any other party for compensatory, punitive, exemplary or consequential damages.

Article 12. Miscellaneous

- 12.00 <u>Governing Law</u>. This Agreement shall be governed by the laws of the United States Government.
- 12.01 Export Control and Biological Select Agents and Toxins. The obligations of the parties to transfer technology to one or more other parties, provide technical information and reports to one or more other parties, and otherwise perform under this Agreement are contingent upon compliance with applicable United States export control laws and regulations. The transfer of certain technical data and commodities may require a license from a cognizant agency of the United States Government or written assurances by the Parties that the Parties shall not export technical data, computer software, or certain commodities to specified foreign countries without prior approval of an appropriate agency of the United States Government. The Parties do not, alone or collectively, represent that a license shall not be required, nor that, if required, it shall be issued. In addition, where applicable, the parties agree to fully comply with all laws, regulations, and guidelines governing biological select agents and toxins.
- 12.02 <u>Independent Contractors</u>. The relationship of the parties to this Agreement is that of independent contractors and not as agents of each other or as joint venturers or partners.
- 12.03 <u>Use of Name or Endorsements</u>. (a) The parties shall not use the name of the other party on any product or service which is directly or indirectly related to either this Agreement or any patent license or assignment agreement which implements this Agreement without the prior approval of the other party. (b) By entering into this Agreement, Laboratory does not directly or indirectly endorse any product or service provided, or to be provided, by Cooperator, its successors, assignees, or licensees. Cooperator shall not in any way imply that this Agreement is an endorsement of any such product or service. Press releases or other public releases of information shall be coordinated between the parties prior to release, except that the Laboratory may release the name of the Cooperator and the title of the research without prior approval from the Cooperator.
- 12.04 <u>Survival of Specified Provisions</u>. The rights specified in provisions of this Agreement covering <u>Patent Rights</u>, <u>Subject Data and Proprietary Information</u>, and <u>Liability</u> shall survive the termination or expiration of this Agreement.
- 12.05 <u>Notices</u>. All notices pertaining to or required by this Agreement shall be in writing and shall be signed by an authorized representative addressed as follows:

If to Cooperator: Georgetown University

Office of Technology Commercialization

3300 Whitehaven Street, N.W. Harris Building, Suite 1500 Washington, DC 20007 Phone: 202-687-2702

Fax: 202-687-3111 (if by Fed Ex or courier)

Or use

Office of Technology Commercialization Georgetown University Box 571408 Washington, DC 20057-1408 (for US Mail)

If to Laboratory: USAMRIID

Business Plans and Programs Office

1425 Porter Street

Fort Detrick, MD 21702-5011

Phone: 301-619-6886 Fax: 301-619-8379

Any party may change such address by notice given to the other in the manner set forth above.

Article 13. <u>Duration of Agreement and Effective Date</u>

- 13.01 <u>Effective Date</u>. This Agreement shall enter into force as of the date it is signed by the last authorized representative of the parties.
- 13.02 <u>Signature Execution</u>. This Agreement may be executed in one or more counterparts by the parties by signature of a person having authority to bind the party, which may be by facsimile signature, each of which when executed and delivered, by facsimile transmission, mail, or email delivery, will be an original and all of which will constitute but one and the same Agreement.
- 13.03 Expiration Date. This Agreement will automatically expire two (2) years from effective date unless it is revised by written notice and mutual agreement.

IN WITNESS WHEREOF, the Parties have caused this agreement to be executed by their duly authorized representatives as follows:

For the Cooperator: Ge	(Organization) (Signature)
/ / Cla	audia Cherney Stewart, Ph.D.

(CRADA) APPENDIX A STATEMENT OF WORK

<u>Title</u>: "Reanalysis and Functional Interpretation of Proteomics Data from Bacterial Cells under Simulated Growth Condition"

Background/Objectives:

Prior bacterial proteomics data needs to be reanalyzed due to the updates to the relevant bacterial protein databases and/or annotations, as well as accumulation of literature information regarding prior unknown genes. The objective of this collaboration is to use the integrated proteomics analysis system, iProXpress developed at PIR, coupled with the current TATRC- funded project, Pathogen Mining System, to facilitate the re-evaluation and functional interpretation and hypothesis formulation from the legacy proteomics data.

Prior 2DGE-MS proteomics data from Burkholderia strains grown under simulated host growth condition will be reanalyzed using iProXpress system for: 1) up-to-date functional assignment of bacterial protein annotations; 2) annotations of homologous proteins from other related pathogens of interests; 3) function and pathway analysis of the bacteria under given growth conditions.

Collaboration:

Laboratory agrees to:

 Provide MS data comprising protein lists and other information of relevance for matched data sets to be re-analyzed by the Pathogen Mining system.

Cooperator agrees to:

- Integrate all available annotations for proteins of Burkholderia and related bacteria into the iProXpress system, including biological pathways and experimental protein-protein interactions.
- Integrate into iProXpress the text mining results on pathogenesis proteins from the Pathogen Mining System.
- Incorporate the experimental Burkholderia proteomics data into the iProXpress system, and perform function and pathway analysis of the data.
- Enhance the iProXpress analysis interface based on the specific needs.

Document Classification for Mining Host Pathogen Protein-Protein Interactions

Abstract

to the heightened concern bioterrorism and emerging/reemerging infectious diseases, a flood of molecular data about human pathogens has been generated and maintained in disparate databases. However, scientific findings regarding these pathogens and their host responses are buried in the growing volume of biomedical literature and there is an urgent need to mine information pertaining to pathogenesis-related proteins especially host-pathogen protein-protein interactions from literature. In this paper, we report our exploration of developing an automated system to identify **MEDLINE** abstracts referring host-pathogen protein-protein interactions. annotated corpus consisting of 1,360 MEDLINE abstracts was generated. With this corpus, we developed and evaluated document classification systems using support vector machines (SVMs). We also investigated the effects of feature selection using the information gain (IG) measure. Document classification systems were designed at two levels, abstract-level and sentence-level. We observed that feature selection was effective not only in reducing the dimensionality of features to build a compact system, but also in improving document classification performance. We also observed abstract-level systems and sentence-level systems yielded classification of MEDLINE abstracts, and the combination of these systems could improve the overall document classification.

1. Introduction

Due to the e heightened concern about bioterrorism and emerging/reemerging infectious diseases, there have been major initiatives for large-scale genomic and proteomic project sto study the basic biology and disease-causing mechanisms of human pathogens [1, 2]. As a result, a flood of molecular datais being generated, but important scientific discoveries regarding these pathogens and their host responses are often buried under the increasing volume of biomedical literature.

Over t he years, biomedical literature m ining advanced greatly. In t his paper, our investig ation focused on the development of an automated system to identify research articles describing pathogenicity and host-pathogen p rotein-protein i nteractions. Our goal is to facilitate literature-based curatio n of pathogenesis-related proteins i n U Knowledgebase (UniProtKB) [3] by i ncorporating pathogenesis i nformation extracted fro m literatu re and promoting basic understanding of vi rulence and pathogenicity fact ors a s well as host-interacting proteins of human pat hogens. Such knowledge will facilitate the development of preventative and therapeutic strategies against human pathogens.

In the following, we first describe the research background and related work. The experimental method is introduced next. We then present the results and discussion, and conclude our work.

2. Background and related work

The task con sidered in the is study is a special

^{*} Equal contribution to the work.

case of identifying papers that desc ribe protein-protein interactions (P PIs). There are several components in de veloping an aut omated literature mining sy stem, i ncluding the construction of an annotated corpus, the selection of features and their representations, and the choice of machine learning algorithms. In the following, we present the research background and related work of each component.

2.1. Constructing annotated corpora from MEDLINE

One step towards constructing annotated corpora from MEDLINE is to select a subset of MEDLINE abstracts. There a re different ways to obtain such subset. One approach is to use keyword search. For example, abstracts select ed for the GEN IA corpus were retrieved from MEDLINE using three MeSH terms, "h uman", "b lood cell" and "t ranscription factor" [4]. An alternative way to obtain a subset is to exploit the use of existing biomedical databases. For example, in order to construct an annotated corpus for the Interaction Article Subtask at the second BioCreative workshop, contents of two existing interaction databases, namely IntAct and MINT, have been exploited [5]. After deriving such subset, domain experts can manually annotate them.

2.2. Feature representation/selection

In order to use machine learning methods, each document nee ds t o be t ransformed i nto a feat ure representation, which is usually a feature vect or. Commonly, features are based on words appearing in the document. Va rious feat ure sel ection t echniques have been explore d to ove rcome the high-dimensionality o f word -based features [6, 7], e.g., Term Frequency (TF), TF * Inverse Document Frequency (IDF), I nformation Gain (IG), M utual Information (MI), or c hi-square statistics. In t his paper, we ex plored IG for feat ure sel ection. I G represents the quantity of information in a feat ure with regard to class p rediction on the base of presence/absence of the feature in a document. Let $\{c_i\}_{i=1}^m$ be a set of categories to be predicted. Then IG of feature w in a document collection is defined as follows:

$$G(w) = E - E_1 - E_2,$$

$$E = -\sum_{i=1}^{m} P(c_i) \log_2 P(c_i),$$

$$E_1 = -P(w) \sum_{i=1}^{m} P(c_i \mid w) \log_2 P(c_i \mid w),$$

$$E_2 = -P(\overline{w}) \sum_{i=1}^m P(c_i \mid \overline{w}) \log_2 P(c_i \mid \overline{w}),$$

where E is the entropy of the document collection; m represents the number of categories; $P(c) = \frac{N_c}{N}$ is occurrence probability of category c, where N represents the number of documents and N_c is the file numbers of class c; $P(w) = \frac{N_w}{N}$ and

 $P(\overline{w}) = \frac{N_{\overline{w}}}{N}$ are occurrence probabilities of presence and absence of w, N_w and $N_{\overline{w}}$ are the file numbers of including and not including feat ure w in the document collection; and finally $P(c \mid w) = \frac{N_{wc}}{N_w}$

and $P(c \mid \overline{w}) = \frac{N_{-w}}{N_{-w}}$ are occu rrence con ditional

probability of the category c on occurrence and absence of term w, where N_{wc} and $N_{\overline{wc}}$ are the file numbers of including and not including term win class c[8]. It is assumed that the larger the IG value of a term is, the more important the term is in classifying documents.

2.3. Machine learning algorithms

A growing number of statistical and probabilistic machine I earning all gorithms have been a pplied to document classification, including K nearest neighbor, Bayesian approache s, decision t rees, sy mbolic r ule learning, and neural networks [9-12]. Here, we chose Support Vector M achines (S VMs), a su pervised learning algorithm proposed by Vladimir Vapnik and his co-workers [13, 14]. It has been widely used for text mining and achieved promising results. Given a training set with n class-labeled instances, (x_1, y_1) , (x_2, y_1) y_2), ..., (x_i, y_i) , ..., (x_n, y_n) , where x_i is a feature vector for the i-th i nstance and $y_i \in \{+1, -1\}$ i ndicates the class, an SVM classifier 1 earns a hyper-plane as a decision boundary in the feature space. The class of an unlabelled in stance x is determined by on which side of the hyperplane x lies. The purpose of training SVM classifiers is to find a hyperplane that has the maximum margin to separate the two classes [16-18].

3. Method

Figure 1 illustrates the overall data flow of the classification system. It consists of several steps including i) generating annotated MEDLINE abstracts, where each abstract was an notated either positive or negative (e.g., +1 or -1) based on its relevance to host-pathogen protein-protein interactions (PH-PPI), ii) conducting machine learning experiments to evaluate different kinds of feature representations and feature selection methods, and iii) implementing a system that a ssigns confidence scores to abstracts based on their PH-PPI relevance.

3.1. Generation of an annotated corpus

The a nnotated co rpus was generated from two different sources. One was from UniProtKB database where the PH-PPI in formation is annotated for the protein entries and the relevant MEDLINE abstracts are cited. If a cited a bstract contains an interaction pair consisting of one host protein and one pathogen protein, it is considered as positive. The other source was from PubMed, from which a set of MEDLINE abstracts was retrieved using keyword searches. Two domain experts reviewed and manually annotated this set, and categorized the abstracts as positive or negative. Additionally, for positive abstracts sentences describing the interactions were highlighted.

3.2. Machine learning

Instead of classifying a document as PH-PPI relevant or not, the machine learning task considered here is to rank a set of documents according to their PH-PPI relevance. We de fined two machine learning tasks. One task is at ab stract level (ALT), which uses the a bstracts to build a system to rank a set of abstracts according to their PH-PPI rele vance. The other is on sentence level (SLT) which ranks all abstracts by considering ti tles and sentences in highlighted sentences in positive abstracts as positive and all se ntences in ne gative abstracts as ne gative. The ranking of a set of abstracts can then be obtained according to the rank of the most relevant sentence in an abstract.

3.2.1. Feature representation/selection

We n ormalized the text by changing nouns in plural forms into singular forms, verbs in past tense into present tense, and replacing nouns and adjectives by their corresponding verbs based on the SPECIALIST lexicon, a component in the Unified Medical Language System (UMLS). We also replaced punctuation marks with spaces and changed

Figure 1. Overall architecture of the study.

uppercase letters to lowercase letters.

After norm alization, we used unigrams and bigrams as fea tures, and the frequencies of unigrams and bigrams as their corresponding feature values. To reduce the dimensionality of the feature space, we used information gain to select features with high IG values. Note that we did not remove features that are stop or rare words in this work.

3.2.2. Machine learning algorithms

We used the SVM light package and cho se a linear function as the kernel [13]. We als o experimented with other types of kernels such as polynomial or radial basis function (RBF), but observed no performance improvement.

3.2.3. Experiments

The experiments were designed to i) compare IG feature selecti on (IG-FS) with no feat ure selection (NO-FS), and ii) compare ALT and SLT. We used 100 runs of 10-fold cross validation. For each run, the sam e 10 fo ld partitions were used for the following four settings: (IG-FS, ALT), (IG-FS, SLT), (NO-FS, ALT), and (NO-FS, SLT). For each setting, we obtained a ranked list consisting of abstracts in the annotated corpus ranked a ccording to the results of the 1 0-fold cross validation e xperiment. The performance was t hen measured using true positive rate (TPR): given rank threshold P and ranked list L, TPR(P, L) is defined as the ratio of the number of true positives ranked as top P in L to P. We selected 18 different rank thresholds: from 10 to 90 (incremented by 10) and fr om 100 to 500 (incremented by 50). In case of IG-FS, we set 20 IG th resholds: 0 to 0.0009

(incremented by 0.0001) a nd f rom 0.0 01 t o 0.01 (incremented by 0.001). For each I G threshold, we ignored all featu res with IG values less th an the threshold when constructing the systems. The average TPR of 100 runs for each setting was computed to compare the perform ance. Confidence intervals at 95% Confidence Level were also computed [15].

3.3. System implementation

As we have discussed, the machine learning task considered here is to rank a set of documents according to their PH-PPI relevance. In order to judge the PH-PPI relevance for any given abstract, we used the following method:

- obtain N score lists by ex ecuting N ru ns of 10-fold c ross val idation using t he c orpus as described in Section 3.2.3 where sco res were ones assigned by SVM classifiers,
- ii) build a SVM classifier C with all i nstances in the corpus,
- iii) for a new a bstract, use classifier C to obtain score S,
- iv) for each sco re list th at was obtained in i) compute the percentage of instances that are positive among the instances with scores larger than S, and
- v) average the above percentage over N score lists and display t he percentage as the rele vance score. The higher the score, the more relevant the abstract.

To test the effectiveness of the proposed method, we used o ne ru n of 1 0-fold cr oss validation a nd measured TPRs for a given relevance score threshold.

4. Result and discussion

Most pat hogen protein-protein interaction (PPI) information annotated in knowledgebases is for viral proteins or PPI within bacteria. We obtained less than 50 positive abstracts on specific bacterial pathogen-human host PPI from knowledge bases such as UniProtKB/Swiss-Protand, IntAct, Brucella Bioinformatics Portal (BBP). Using keywords "bacterial", "host", "pathogen", and "interaction", we retrieved around 214,000 abstracts, and we obtained 1,225 negative abstracts and 99 positive abstracts after manual annotation. Merging the two sets, the annotated corpus consists of 1,225 negative abstracts and 135 positive ones.

Figure 2 shows t he relationship bet ween I G threshold and TPR averaged over 100 runs. The IG threshold of 0 corresponds to no feat ure selection (NO-FS). From Figure 2, we can see that for IG

Figure 2. The relationship b etween IG th reshold and TPR averaged over 100 runs in (IG-TF, ALT) and (IG-FS, SLT).

Figure 3. Combination result of (IG-FS, ALT)-0.001 and (IG-FS, SLT)-0.001.

thresholds between 0.001 and 0.005, the TPR s are comparable to the one without feature selection (i.e. NO-FS). However, the number of features u sed for classifiers with feature selection decrease s dramatically. For example, in (IG-FS, AL T) with threshold 0.002 and (IG-FS, SLT) with threshold 0.001, the number of features after feature selection is reduced to only 10% (around 10,000) of the original (over 100,000).

Table 1. The detailed TPRs with the corresponding 95% confidence intervals computed from 100 runs for (IG-FS, ALT), (IG-FS, SLT), (NO-FS, ALT) with IG threshold 0.002, and (NO-FS, SLT) with IG threshold 0.001. RT stands for rank threshold.

	(0.237, 0.239)	(0.235, 0.237)	(0.231, 0.233)	(0.228, 0.230)		

Table 1 shows t he detailed results of fo ur settings: (NO-FS, ALT), (NO-FS, SLT), (IG-FS, ALT) with I G threshold 0.002, and (I G-FS, S LT) with I G threshold 0.001. For example, among top 50 abstracts, there are 76.8%, 73.7%, 80.7%, and 74 .5% of the abstracts are positive for (NO-FS, ALT), (NO-FS, SLT), (IG-FS, ALT), and (IG-FS, LT), re spectively. The avera ge TPRs us ually decrease when the rank thresholds i ncrease. T he perform ance of sentence-level syste ms is comparable t o that of abstract-level syste ms when the rank threshold is small (e.g., 10 or 20). When the rank threshold (e.g., \geq 20) is lar ge, abstract-level systems tend to p erform better.

Table 2 s hows t he performance of the true positive rate when implementing the system using (IG-FS, ALT) with IG threshold 0.002 and the number of runs as 5. Given a relevance score threshold 0.5, the true positive rate is 50.7% which indicates that if an abstract receives a relevance score of larger than

Table 2. The performance of the implementation.

Threshold	Total	Positive	TPR
0	1,360	135	0.099
0.1	1,185	118	0.099
0.2	519	106	0.204
0.3	304	93	0.306
0.4	207	82	0.396
0.5	136	69	0.507
0.6	96	63	0.656
0.7	69	52	0.754
0.8	41	30	0.732
0.9	8	7	0.875

0.5, the chance of the abstract to be positive is 50.7%.

Even sentence-level systems perform inferior to abstract-level systems, but one a dvantage of them is that sente nees desc ribing protein interact ions are automatically highlighted. We can highlight sentences

(and titles) yielding t he h ighest rank s am ong sentences within the ab stract when presenting the results to e nd-users. For example, for (IG-FS, SLT) with IG thr eshold 0.001, t he average number of positive abstracts is 17 (or 37) among the top 20 (or 50) ab stracts. Among those positive abstracts, an average of 13 (or 26) abstracts have the highlighted sentences ranked as the highest among all sentences in the corresponding a bstract by the sent ence-level systems, and a naverage of 16 (or 33) abstracts have the highlighted sentences ranked as the highest or the second highest.

We also noticed that sentence-level systems and abstract-level systems behave differently. The finding is con sistent with t he work of Ding et al where different text units (e.g., abstracts, se ntences, or phrases) were in vestigated for in formation retriev al [16]. Given rank threshold 10, and IG threshold 0.001, the av erage number of overlapped true po sitives between sentence-level and abstract-level systems is around 4. We c hecked the com bination of sentence-level and a bstract-level sys tems by averaging the ranks of sentence -level and abstract-level. Figure 3 s hows t he result. There is some im provement of t he performance aft er combination.

5. Conclusion

We have reported a study of constructing an automated system that can detect the host pathogen protein-protein interaction relevance of MEDLINE abstracts. The results indicated that fe ature selection can reduce the number of features at least 10 folds with no or little sacrifice of performance. Additionally, the majority of the highlighted sentences are ranked as the first or second among all sentences in the corresponding a bstracts. We conclude that au tomated systems can be built for retrieving abstracts and highlighting sentences based on their relevance to host pathogen protein-protein interaction.

Summary

Objective: Scientific findings regarding human pathogens and their host responses are buried in the growing volume of biomedical literature and there is an urgent need to mine information pertaining to pathogenesis-related proteins especially host pathogen protein-protein interactions (HP-PPIs) from literature.

Methods: In this paper, we report our exploration of developing an automated system to identify MEDLINE abstracts referring to HP-PPIs. An annotated corpus consisting of 1360 MEDLINE abstracts was generated. With this corpus, we developed and evaluated document classification systems using support vector machines (SVMs). We also investigated the effects of three feature selection methods (information gain, mutual information, and χ^2 test). The performance was measured using Normalized Discounted Cumulative Gain (NDCG) and Positive Predictive Value (PPV) and all measures were obtained through 10-fold cross validation.

²Equal contribution to the work

Results: NDCG measures for classification systems using all features or a subset of features selected using information gain and χ^2 range from 0.83 to 0.89 while classification systems built based on features selected using mutual information had relatively lower NDCG measures. The classification system achieved a PPV of 50.7% for the top 10% ranked documents comparing to a baseline PPV of 10.0%.

Conclusions: Our results indicate that document classification systems can be constructed to efficiently retrieve HP-PPI related documents. Feature selection was effective in reducing the dimensionality of features to build a compact system.

Key words: document classification, host pathogen protein-protein interaction, feature selection, literature mining

1. Introduction

The causative agents of infectious diseases consist of a great diversity of agents including bacteria, viruses, fungi, helminthes and protozoa. Because of the development of new molecular biology assays, there has been continuing progress in the study of pathogenicity mechanism. Meanwhile, due to the heightened concern about bioterrorism and emerging/reemerging infectious diseases, there have been major initiatives for large-scale genomic and proteomic projects to study the basic biology and disease-causing mechanisms of human pathogens [1, 2]. As a result, a flood of molecular data is being generated, but important scientific discoveries regarding these pathogens and their host responses are often buried under the increasing volume of biomedical literature. It was reported that the growth of peer-reviewed literature in MEDLINE is exponential [3]. With this volume of publication, it is very difficult or even impossible for biologists to find or assimilate the relevant publications of pathogenicity. To effectively manage the knowledge of pathogens and to better understand the pathogens, an automated text mining system that can extract pathogen related information from the scientific literature is highly desired.

In this paper, we focus on the development of an automated text mining system to identify research articles describing host pathogen protein-protein interactions (HP-PPIs). We focus on pathogens that are bacteria. By reviewing thousands of documents in MEDLINE, we constructed a corpus consist-

ing of 1360 abstracts where 135 abstracts are HP-PPI relevant (i.e., positive) and the remaining are not HP-PPI relevant (i.e., negative). The corpus was then used to train a machine learning classifier to identify HP-PPI related articles where samples are abstracts and features are words or phrases in the abstracts. Three feature selection methods, information gain (IG), χ^2 test, and specific mutual information (SI) were compared for reducing the high dimensionality of the feature space.

2. Background and related work

The task considered in this study is a special case of identifying papers that describe protein-protein interactions (PPIs). There are several components in developing an automated literature mining system, including the construction of an annotated corpus, the selection of features and their representations, and the choice of machine learning algorithms. In the following, we present the research background and related work of each component.

2.1. Construction of annotated corpora from MEDLINE

One step towards constructing annotated corpora from MEDLINE is to select a subset of MEDLINE abstracts. There are different ways to obtain such subset. One approach is to use keyword search. For example, abstracts selected for the GENIA corpus were retrieved from MEDLINE using three MeSH terms, "human", "blood cell" and "transcription factor" [4]. An alternative way to obtain a subset is to exploit the use of existing biomedical databases. For example, in order to construct an annotated corpus for the Interaction Article Subtask at the second BioCreative workshop, contents of two existing interaction databases, namely IntAct and MINT, have been exploited [5]. After deriving such subset, domain experts can manually annotate them.

2.2. Feature representation/selection

In order to use machine learning methods, usually each document needs to be transformed into a feature vector. Commonly, features are based on words appearing in the document. Various feature selection techniques have been explored to overcome the high-dimensionality of word-based features. In this paper, three widely used feature selection methods, information gain (IG), specific mutual information (SI), and χ^2 test, were applied and compared.

IG represents the quantity of information in a feature with regard to class prediction on the basis of presence/absence of the feature in a document. Let $\{c_i\}_{i=1}^m$ be a set of categories to be predicted. Then the IG value of feature t in a document collection IG(t) is defined as follows:

$$IG(t) = E - E_1 - E_2,$$
 (1)

$$E = -\sum_{i=1}^{m} P(c_i) \log_2 P(c_i),$$
 (2)

$$E_1 = -P(t) \sum_{i=1}^{m} P(c_i|t) \log_2 P(c_i|t),$$
(3)

$$E_2 = -P(\bar{t}) \sum_{i=1}^{m} P(c_i|\bar{t}) \log_2 P(c_i|\bar{t}), \tag{4}$$

where E is the entropy of the document collection; P(c) is the occurrence probability of category c; P(t) and $P(\bar{t})$ are the occurrence probabilities of presence and absence of t; and finally P(c|t) and $P(c|\bar{t})$ are the conditional probabilities of the occurrence of category c with or without feature t. The larger IG(t) is, the more important t is. By calculating IG value for each variable appearing in the abstracts, a rank list for all the variables can be obtained. Given a threshold value, features with IG values ranked high are selected to build classifiers.

In information theory, the SI of two random variables has been used to describe the mutual dependence of the two variables. In text mining, the SI of feature t in category c, SI(t,c), can be defined as:

$$SI(t,c) = \log \frac{p(t,c)}{p(t)p(c)},$$
(5)

where p(t,c) is the joint occurrence probability of t and c; and p(t) and p(c) are occurrence probabilities of t and c, respectively. Then the mutual information of t, MI(t), can be defined as [6]:

$$MI(t) = \sum_{i=1}^{m} p(t, c_i) SI(t, c_i) + \sum_{i=1}^{m} p(\bar{t}, c_i) SI(\bar{t}, c_i)$$
 (6)

The definition here yields the equivalence of MI(t) and IG(t) [7]. To distinguish from IG, Yang and Pedersen computed SI only based on the presence of

a specific term. The feature value of feature t was defined in two alternative ways [7]:

$$MI_MAX(t) = \max_{i=1}^{m} \{SI(t, c_i)\},$$
 (7)

$$MI_AVG(t) = \sum_{i=1}^{m} p(c_i)SI(t, c_i).$$
(8)

Feature words were ranked accordingly and only the top-ranked features were used to build classifiers.

The third feature selection method we applied is χ^2 test which is commonly used to test the independence of two variables. Here, the two variables are feature t and document class c. The null hypothesis is that the occurrence of t and the occurrence of c are independent. The statistics of χ^2 is defined as:

$$\chi^{2}(c,t) = \sum_{ec \in \{0,1\}} \sum_{et \in \{0,1\}} \frac{(O_{et,ec} - E_{et,ec})^{2}}{E_{et,ec}},$$
(9)

where χ^2 is the test statistic that asymptotically approaches a χ^2 distribution. O is an observed frequency; E is an expected (theoretical) frequency, asserted by the null hypothesis. Similarly, features are ranked with respect to their χ^2 scores, and the top-ranked features in are selected to train the classifier, since a high χ^2 score indicates that the hypothesis of independence between the feature and the class is incorrect.

3. Method and experimental design

Figure 1 illustrates the overall data flow of constructing the classification system. It consists of several steps:

- Generating an annotated MEDLINE corpus: each abstract was annotated either positive or negative based on its relevance to HP-PPI;
- Reducing the high dimensional feature space: three feature selection methods (IG, MI, and χ^2 test), and the resulting features were applied to train classifiers;
- Evaluating the performance: ten-fold cross-validation was used to evaluate the performance.

Generation of Annotated Data UniProt Knowledgebase Retrieve positive papers from Categorize abstracts retrieved using knowledge bases keywords into positive and negative Annotated MEDLINE abstracts Document classification SVM Classifier Ranked list generation eature representation & selection construction based on classification System implementation Abstract SVM Classifier Gold standard Score assignment

Figure 1: Experimental design

3.1. Annotated data generation

In order to gather HP-PPI related abstracts, two biomedical databases were investigated. First, a data file was downloaded from UniProtKB, where the HP-PPI information is annotated for the protein entries, and the relevant MEDLINE abstracts are cited. If a cited abstract contains HP-PPI information, it is considered as positive, while unrelated abstracts are labeled as negative. Second, a set of MEDLINE abstracts obtained by keyword searching were reviewed by two domain experts. The pathogen related and unrelated abstracts were tagged manually. Mining these two databases resulted in 135 positive abstracts and 1225 negative abstracts, with a total of 1360 samples.

3.2. Feature representation and selection

Each document was normalized by changing lexical variants to their base forms and replacing nouns and adjectives by their corresponding verbs based on the SPECIALIST lexicon, a component of the Unified Medical Language System (UMLS) [8]. We also replaced punctuation marks with spaces, and changed uppercase letters to lowercase letters. After normalization, we used uni-grams and bi-grams as features. An n-gram is a subsequence of n items

from a given sequence. Accordingly, our features included every single normalized word (uni-gram) in the corpus and every two neighboring normalized words (bi-gram) present in the corpus. The frequency of a uni- and bi-gram in each abstract was used as the feature value. Three feature selection methods introduced previously were applied. Additionally, for mutual information, we experimented with different document frequency thresholds where features with frequency lower than the given threshold were removed.

3.3. Document classification

A growing number of statistical and probabilistic machine learning algorithms have been applied to document classification, including K nearest neighbor, Bayesian approaches, decision trees, symbolic rule learning, and neural networks [9]. Here, we chose Support Vector Machines (SVMs), a supervised learning algorithm proposed by Vapnik and his co-workers [10, 11]. It has been widely used for text mining and achieved promising results. The purpose of training SVM classifiers is to find a hyperplane to separate the two classes with the maximum margin [10, 11]. SVMlight, by Joachims, is one of the most widely used SVM classification and regression packages. The algorithms used in SVMlight has scalable memory requirements and can handle problems with many thousands of support vectors efficiently [12, 13]. In the present project, we used the SVMlight package and chose the linear kernel. We also experimented with other types of kernels such as polynomial or radial basis function (RBF), but observed no performance improvement.

3.4. Performance evaluation

The performance was evaluated through 10-fold cross validation. In 10-fold cross validation, an annotated corpus is partitioned into 10 portions, and each portion is used to evaluate a classifier trained with the remaining 9 portions. Instead of traditional binary classification, for each run, we generated a rank list based on the classification scores.

The following metrics were used to measure the performance:

• Simplified Normalized Discounted Cumulative Gain (NDCG).

$$NDCG = Z_k \sum_{m=1}^{k} \frac{2^{R_m} - 1}{\log(1+m)}$$
 (10)

where Z_k is a normalization factor calculated to make it so that the NDCG of a perfect ranking at k is 1. R_m is the relevance of an abstract

to HP-PPI, either 1 (relevant) or 0 (irrelevant), m is the rank of the abstract in the final list, and k is the total number of the abstract [6]. The advantage of NDCG is that among the classifiers with same accuracy, the classifier which can rank the true positive literature higher will be awarded more.

- Receiver Operating Characteristic curve (ROC curve). This is a graphical plot of the true positive rate against the false positive rate for the different possible cut-points of a binary classifier system [14].
- Another measure used is the Positive Predictive Value (PPV) [15] which is the same as precision (i.e., the probability of predicted positives to be true positives) given a cut-point of a binary classifier system.

3.5. System implementation

As we have discussed, the machine learning task considered here is to rank a set of documents according to their PH-PPI relevance. In order to judge the PH-PPI relevance for any given abstract, we used the following method:

- \bullet obtain N score lists by executing N runs of 10-fold cross validation using the corpus where scores were ones assigned by SVM classifiers,
- build an SVM classifier C with all documents in the corpus,
- for a new abstract d, use classifier C to obtain a score S(d) for d,
- for each score list that was obtained, compute the percentage of documents that are positive among the documents with scores larger than S(d), and
- average the above percentage over N score lists and display the percentage as the relevance score. The higher the score, the more relevant the abstract.

To test the effectiveness of the proposed method, we used one run of 10-fold cross validation and measured PPVs for a given relevance score threshold.

4. Results and discussion

4.1. Document frequency for specific mutual information

Figures 2 and 3 display the performance of SVM classifiers on our corpus after using MI_MAX and MI_AVG as the feature selection method with different document frequency thresholds. In general, MI_MAX has better performance than MI_AVG. The classification results showed that the NDCG (normalized discounted cumulative gain) value of both MI_MAX and MI_AVG generally decreases as the number of features decreased, which can be explained by the smaller amount of information (fewer features) recruited by the classifier. However, the performance of MLMAX was improved as the document frequency threshold increased. By setting the threshold of document frequency, low frequency terms with document frequency less than the threshold can be removed from the feature space. In our case, the NDCG of the classifier based on MLMAX remains above 0.83 even with only 1000 feature terms if the document frequency threshold was no less than 3, while the NDCG of other classifiers with threshold of 1 and 2 was less than 0.82 with 3000 feature terms. Therefore, setting document frequency threshold is a crucial step for applying MI_MAX. But for MI_AVG, the performance was not improved by increasing the threshold of document frequency. To calculate the average mutual information for each term, a weight was assigned to each term for each class. Here, we use the occurrence probability of each class as the weight. Due to the imbalanced distribution of classes (only 10%documents are positive), the weight for the terms in positive abstracts would be 0.1, much lower than the terms in negative abstracts. Consequently, the informative terms in positive documents were swamped by the terms in negatives. In our project, the features of positive documents are more helpful in recognizing the pattern. Together, the poor performance of ML-AVG and the distinct characteristics from MI_MAX were caused by the bias towards low-frequency words and the bias towards words in negative abstracts.

4.2. Comparison of feature selection methods

Table 1 and Figure 4 show the comparison results of three feature selection methods. When there were more than 4000 feature terms, MLMAX, IG, and CHI had similar performance. But as the number of features used in the classifier decreases to less than 4000, the performance of MLMAX declines much faster than IG and CHI. The classifier curve goes to the minimum 0.769 if the classifier used 100 terms selected based on MLMAX, while using

Table 1: Average NDCG of classifiers with feature selection

Figure 4: Comparison results of three feature selection methods

the same number of features selected from information gain or χ^2 test the classifier's NDCG is still above the line of 0.831, indicating MLMAX does not have comparable performance to the other two methods: information gain and χ^2 test.

4.3. Comparison of systems with and without feature selection

The overall performance of no feature selection, information gain, and χ^2 test is shown in Figure 5. We found that as the feature number became greater than 500, the performance of the IG and χ^2 test were comparable to that of no feature selection. Both IG and χ^2 test outperformed no feature selection by virtue of the much lower dimensional feature spaces they used. These two feature selection methods selected a small number of variables and then generated compact models.

In implementation, each abstract in the test dataset was assigned a score by an SVM classifier, and the abstracts were ordered by those scores. The higher the score, the more likely the abstract to be positive. Therefore, given a rank threshold N, the abstracts with rank above N were classified as positive abstracts, while the abstracts with lower rank were categorized as negative. Given a series of rank thresholds, ROC curves of different classifiers built upon no feature selection, information gain, and χ^2 test were shown in Figure 6. All three curves approach the left-hand border and then the top border of the ROC space, located far from the no-discrimination line, indicating competent classification capability. The χ^2 curve lies closer to the 45-degree diagonal of the ROC space, suggesting poor performance. Figure 7 shows the positive predictive value of three models at rank thresholds of 25, 50, 75, 100, and 135. A classifier with no feature selection gave the best performance among the three at each threshold because it utilized all uni-grams and bi-grams as features, thereby using as much information as possible from the samples. However, classifiers build upon information gain and χ^2 achieved comparable results with much lower cost. The number of term used was reduced to 2000 (a 98.3% reduction).

4.4. Evaluation of implementation

Table 2 shows the performance of PPVs when implementing the system using information gain (IG) threshold of 0.002 and the number of runs parameter is set to 5. Given a relevance score threshold 0.5, PPV is 50.7% which indicates that if an abstract receives relevance score higher than 0.5,

Figure 5: Performance of no feature selection vs. feature selection

Threshold	TOTAL	TP	PPV
0	1360	135	0.099
0.1	1185	118	0.099
0.2	519	106	0.204
0.3	304	93	0.306
0.4	207	82	0.396
0.5	136	69	0.507
0.6	96	63	0.656
0.7	69	52	0.754
0.8	41	30	0.732
0.9	8	7	0.875

Table 2: The performance of implementation

Figure 6: Receiver operating characteristic curve of different classifiers

Figure 7: The positive predictive value of different classifiers

the probability of the abstract to be positive is 50.7%, which is much higher than the random chance to select positive abstracts (9.9%; 135 out of 1360).

5. Conclusions

In summary, we built a text mining system that retrieves MEDLINE abstracts pertaining to host-pathogen protein-protein interaction. We manually constructed a literature corpus consisting of 1360 Medline abstracts, where 135 are HP-PPI related and the remaining ones are HP-PPI unrelated. This corpus was used to build automated text categorization system that classifies MEDLINE abstracts as HP-PPI related or not. As a classification algorithm, SVM was used. In addition, three feature selection methods (IG, MI, and χ^2 test) were considered to reduce the high dimensionality of the feature space. Among them, IG and χ^2 test were found effective in reducing the dimensionality and, thus, in building a compact system. Our results indicate that an automated document classification system can help curators search and retrieve HP-PPI related biomedical literature.

Abstract

The ever-increasing scientific literature and the exponential growth of large-scale molecular data have prompted active research in biological text mining to facilitate literature-based curation of molecular databases. Meanwhile, systems biology and bioontologies are emerging as critical tools in biological research where complex data in disparate resources are generated, integrated and analyzed. Both rely on literature for data annotation and analysis. The challenges facing us are to develop broadly utilized text mining tools and systems, and to bring together developer and user communities for system development and evaluation. We describe a framework for linking text mining tools with ontology and systems biology, extending from a previously developed text mining resource, iProLINK. We focus on molecular and ontological resources, including genes/proteins, proteinprotein interaction (PPI), and Protein Ontology. The framework consists of two major components: a user interface for text mining of PPI from an integrated tool server and software modules to allow text mining outputs to be created, ranked, and used by the community. Use cases are presented for assessing the gaps and making recommendations for future development.

1. Introduction: current status of text mining as an enabling tool for biology

The biological literature represents the repository of biological knowledge. As biology becomes more dependent on information technology, there has been an explosion of computable resources and databases [1], e.g. GenBank, UniProt, model organism databases, and systems biology databases, e.g., Reactome, KEGG, that

capture much of the structured information on sequence and functional data. It becomes critical to link these data sources to their associated context, e.g., experimental methods and evidence. Such information is largely buried in the literature and it has become prohibitively expensive for curators to keep up with its growth.

1.1. Text mining resource development

Most of the work in biomedical text mining over the past decade has focused on solving specific problems, often using task-tailored and private datasets, which were rarely reused. As more research groups began to make resources publicly available, there have been a number of projects, initiatives and organizations dedicated to building and providing access to biomedical text mining resources, such as those listed at the National Center for Text Mining at UK (http://www.nactem.ac.uk) and Text Mining Group at the Center for Computational Pharmacology (http://compbio.uchsc.edu/ccp/corpora).

Researchers at PIR have contributed to this effort by developing a literature mining resource, iProLINK, to support text mining and NLP research for bibliography mapping (references cited in a protein entry), annotation extraction, entity recognition and protein ontology development [2]. The data sources for bibliography mapping and feature evidence attribution include mapped citations and annotation-tagged literature corpora [3]. The data sources for entity recognition and ontology development include protein name dictionaries and protein name-tagged literature corpora along with tagging guidelines [4]. These curated corpora have been used for training and benchmarking text mining tools such as RLIMS-P, an information extraction tool for protein phosphorylation [5]. iProLINK also provides the online BioThesaurus, a large collection of gene/protein names with UniProt entry associations [6].

1.2. Text mining critical evaluations

^{*} Corresponding author.

As the BioCreative [7, 8] and TREC Genomics track [9] evaluations have shown, common evaluations are important to create an active research community and to accelerate the research progress. There have been two BioCreative workshops to date, with 27 groups participating in the first [7], and 44 groups participating in the second [8]. These workshops have focused on tasks relevant to the biological curation community, including identification of gene mention (GM) and gene normalization (GN), and on more advanced tasks. For BioCreative I, the focus was on functional annotation, including linkage of evidence passages to support GO annotations for proteins in full text articles. For BioCreative II, the advanced task focused on extraction of protein-protein interaction (PPI) information, using "gold standard" data provided by the MINT and IntAct databases. The BioCreative evaluations have driven progress in biomedical text mining and have led to release of annotated data collections for further evaluation (http://BioCreative.sourceforge.net).

1.3. Text mining tool integration

It has been observed that "accurate and diverse" tools targeting the same application area can make a combination system outperform a single constituent tool [10, 11]. For example, Si et al. [12] combined systems that participated in the JNLPBA shared task (recognition of five types of entities in abstracts), and reported excellent performance using Conditional Random Fields (CRFs). Similarly [13, 14] reported results obtained by combining 21 systems from the BioCreative II GM task, and reported an F-measure over 90% using CRFs.

A major accomplishment of BioCreative II was the establishment of BioCreative MetaServer (BCMS, http://bcms.bioinfo.cnio.es/) [15], a prototype platform that combines text mining services from multiple groups, currently covers some major tasks from BioCreative II, including GM/GN, taxon classification and PPI identification, and provides annotations from 13 servers for the BioCreative corpus of MEDLINE abstracts.

1.4. Text mining standards development

Common standards for data exchange and tool integration are critical for text mining. Currently there is a lack of formal standards and candidates for de facto standards are not widely accepted at this time. The first concrete proposal for a data exchange standard for biomedical text processing was GPML, the GENIA Project Mark-up Language [16]. A corpus annotated in this format has been released in multiple revisions and has experienced significant acceptance in the text mining community [17], but tool producers have not embraced it as an output format. For the tool integration, there has been considerable amount of interest in the Unstructured Information Management Architecture (UIMA) [18-21],

but it is not considered the de facto standard for tool integration yet. A meeting held in conjunction with the recent BioNLP 2008 workshop concluded that there was little hope for convergence on a common format in the near future, and that the best that could be hoped for at this time with respect to corpora and data exchange is that corpus builders produce formats that can be interconverted—no small feat in itself [22].

1.5. Motivation for a community framework

Even with advancements in tool and system development and the growing collaborative efforts of the text mining community, literature mining tools are still not broadly used by biological communities. Such a gap is partly due to intrinsic complexity of biological text for mining, and partly to the lack of close interactions between the text mining and the user communities, represented by biology researchers and curators.

BioCreative I and II focused on critical assessment of text mining tool performance on individual tasks involved in the overall molecular data curation process. The next step is to link these tools together to provide an environment that supports end users. The communities represented by biologists/curators and tool developers can be brought together by a common interface and through community workshops. In this paper, we describe an extended iProLINK framework that aims to link the three communities, allowing text mining tools to be evaluated and adopted by the broad communities. This work builds on four threads of research: the previous iProLINK text mining resource; BioCreative evaluations; tools and data resources developed under BioCreative, in particular the vision of a MetaServer to provide text mining services to users; and work at PIR focused on building a framework for the capture of PPI, including post-translational modifications (PTM). We present several case studies that illustrate the mutual benefit each community can gain from the others.

2. Linking text mining with ontology and systems biology: a basic framework

2.1. iProLINK framework

An overview of the iProLINK framework is shown in Figure 1. It contains two major components: text mining tools, and the interface that links the text mining to ontology and systems biology communities. Text mining tools are integrated into a metaserver that will generate text mining results, and the user interface will display ranked outputs (circle #1) and the visualized protein networks (#2) based on the output. The interface also allows users/curators to curate the text mining results (#1) and make assertions on the extracted knowledge. The curated information is used for or captured in ontologies (e.g. Protein Ontology) (#3) and

knowledgebases (#4), and is also saved in a curated literature corpus (#6) used for improving the text mining output ranking (#7) and for enhancing text mining tool development (#8). The systems biology data can also be used to help assertion of the text mining results (#5).

Figure 1. Overview of the iProLINK framework

2.2. Linking text mining, ontology and systems biology for protein-protein interactions

PPI generally refers to physical associations of two protein objects, stable or transient, such as in protein complexes or in signaling cascades. There are many types of PPIs; in this context, we define PPI as protein pairs with either direct or indirect associations such as through intermediate steps.

Text mining. The text mining tasks for iProLINK include integration of tools, presently covering gene or protein mention, gene or protein normalization, and information retrieval and extraction of PPI, including PTMs such as phosphorylation (an interaction between a protein substrate and a protein kinase). There are a number of tools for these tasks, including those

participating in the BioCreative I and II challenge evaluations, and others such as RLIMS-P.

Ontology. Open Biological Ontologies (OBO) Foundry is a collaborative effort for coordinating various biological ontology development projects and for fostering common standards in OBO development [23]. The curation of the content of ontologies, especially those related to genes or proteins, e.g. specific splice or modified forms of gene products in Protein Ontology (PRO) [24], relies heavily on literature information. In particular, protein PTM and PPI text mining will help annotate protein nodes (terms) by identifying specific phosphorylated forms and adding PPI information as attributes to PRO forms.

Systems biology. Molecular databases represent structured knowledge of genes/proteins, such as UniProt, and biological pathway and PPI databases. Annotation of those databases and utilization of the annotations for large-scale omics data analysis are an integral part of systems biology, e.g., iProXpress, an expression analysis system for systems biology [25]. Text mining results can be used to infer or add more evidence to pathway and network analysis results derived from systems biology data; conversely, large-scale data can be used to support the text mining results of PPI information.

3. iProLINK use case analysis

3.1. PPI text mining for generation of protein networks

There are several PPI text mining tools, such as PIE [26] and iHOP [27], both as part of the BCMS. We use these two tools to illustrate PPI text mining results and how they can be used for generation of protein networks. As shown in Figure 2, the tools typically highlight or underline sentences containing the PPI, with protein pairs and words for relations highlighted (bold or colors). There are 11 pairs of PPI instances in this abstract,

including the title. Most (8/11) are detected by one or the other tool, and most

(9/11) are direct PPIs. The visualized PPI network allows users to more efficiently mine proteins of interest and their interacting partners. Based on the binary relations (edge) between interacting partners (node), we used Cytoscape [28] to display these mined PPIs in a single protein network (Figure 2, lower right). It shows that Galpha(o) is a

Figure 2. PPI text mining results for the construction of protein network

major hub protein that interacts with six other proteins directly or indirectly. Rap1GAP is another important protein that interacts with three other proteins. The UniProt IDs for the protein nodes are displayed with mouse-over, and the text evidence for relations (edges) between protein nodes is also visualized by mouse-over (PMID in this case). The protein networks can also be built from multiple abstracts either through batch retrieval (section 3.3) or by gene/protein name searches. The latter would be a more useful feature in analyzing PPI of particular proteins based on PubMed searches.

The essential requirements for the interface in PPI text mining and protein network generation are to 1) provide ranking of PPI outputs based on scores or confidence levels for each protein pairs; 2) support user/curator feedback on the output ranking and content, and an ability to save the output in standard data formats compatible to other software tools such as Cytoscape and OBO editor; and 3) display the protein nodes and edges with weightings and evidence attributions.

3.2. PTM text mining for Protein Ontology form curation

The Protein Ontology is designed to describe the relationships of proteins and protein evolutionary classes, to delineate the multiple protein forms of a gene locus, and to interconnect existing ontologies [24]. Multiple protein forms include splice isoforms and various PTMs. Knowledge of protein splice forms and modifications are mostly embedded in the literature, thus text mining of such information greatly facilitates the curation of PRO nodes (terms) and relations. Protein phosphorylation is a common type of PTM, and proteins with distinct phosphorylated residue(s) represent unique protein forms. RLIMS-P is designed to extract the three protein phosphorylation objects: kinase, substrate and the phosphorylation sites/residues. The kinase and substrate interaction is a special case of PPI that can be mined by

Figure 3. RLIMS-P text mining for Protein Ontology curation

text mining tools, such as PIE. However, RLIMS-P also extracts phosphorylation sites, useful for PRO curation.

Figure 3 shows the output of the RLIMS-P extracted PPI and phosphorylation sites (PMID: 18003885), which can be directly used for curation of the protein node, RUNX1, a transcription factor. RLIMS-P outputs contain a summary table for the extracted PPI and evidencetagged sentences in the abstract. One of the 11 isoforms. AML-1G, of human RUNX1 is described in PRO format as being phosphorylated at Ser 48, 303, and 424; the specific PTM type (phosphorylation at L-serine) is annotated using the PSI-MOD ontology (MOD:00046) (Figure 3). Experimental PPI information can also be used for annotating properties to protein forms in PRO, e.g., the associated functions of the phosphorylated form of RUNX1 in this paper can be annotated for AML-1G. e.g., "increases transactivation potency and stimulates cell proliferation". The RLIMS-P outputs need to be saved in standard formats, such as OWL or OBO, for protein network display and PRO curation.

Protein 1	Protein 2	Rel.	PMID	Tool	Galpha(b)
Galpha(o)	Rap1GAP	I	10419452	PIE	0
Cdc2	Rap1GAP	Р	8048970	RLIMSP	Rap1GAP
Cdc2	BAD	Р	12049737	RLIMSP PIE	0 14-3-3
BAD	14-3-3		12049737	RLIMSP PIE	Cdc2 Phospho-S136
BAD	14-3-3	1	10949026	RLIMSP PIE	Phospho-S128
BAD	Bcl-xL	I	8929531	PIE	non/under- phosphorylated BcI-xL

Figure 4. Text mining summary and network generation of PPI, including general "Interaction" (I) and protein phosphorlyation (P)

3.3. PPI text mining for systems biology

Systems biology data include gene/protein databases and large-scale omics data repositories. Annotation and analysis of systems biology data can benefit from PPI text mining. The protein network in Figure 2 contains the

Rap1-MAPK pathway, which is modulated by $G\alpha(o)$ -Rap1GAP interaction. Other papers describe the activation of Rap1GAP through phosphorylation by Cdc2 (CDK1), which also phosphorylates the BAD protein at distinct site (Ser128) (Figure 4). Interestingly, distinct forms of BAD interact with different partners.

When combining PPI mining results from Figure 2 and 4, a larger protein network can be generated, showing four highly-connected protein nodes— $G\alpha(o)$, Rap1GAP, Cdc2 and BAD (Figure 5A). Compared to a pathway diagram

based on the analysis of a proteomics dataset [29] (Figure 5B), this text mining-based PPI network graph not only provides literature evidence for the interactions shown in the pathway map (e.g., GNAO2-Rap1GAP, Rap1GAP-Rap1), but also reveals a missing interacting protein pair (Cdc2-Rap1GAP) in the pathway (red dashed arrow), as well as missing partners of BAD protein (14-3-3 and Bcl-xL).

Figure 5. Text mining of PPI (A) for annotation and analysis of systems biology data (B)

3.4. PPI text mining supported by systems biology data

Systems biology data can also strengthen PPI text mining results. Figure 6 shows an example where PPI proteomic data from large-scale immunoprecipitation are linked to text mining results. The Sp1-p38 interaction from a proteomics experiment was deposited in IntAct, one of the PPI and pathway databases integrated into the iProXpress underlying data warehouse. This information supports the protein network derived from text mining, showing p38-Sp1 interaction and activation of filamin-A.

The display of protein networks will allow linkage of protein nodes to pathway maps or high-throughput PPI data from molecular databases. Alternatively, saved text mining outputs can also be integrated into users' pathway and network analysis pipeline.

Figure 6. Systems biology data support the text mining of Sp1-p38 interaction (PMID: 12324467)

4. Future work

From above case studies, we have identified major gaps between the text mining and the ontology and systems biology communities that need to be addressed:

Standards development. Text mining standards include those of data exchange and tool integration. Tool integration involves issues such as process control and preserving state information as well as a mechanism for exchanging data. Standards must also support data exchange, including both syntactic standards (e.g., XML or SGML tags) and semantic standards – perhaps based on widely accepted biological resources, such as EntrezGene and UniProt.

User interface requirements. The web interface is a major component of the iProLINK framework for the communities. The new interface will allow biologists to browse, curate, and save the text mined PPI/PTM information. The interface should provide several key functionalities: 1) The output from multiple text mining tools should be ranked, and the display of protein network and associated text evidence should be weighted; 2) Users should be able to edit the text mining results, and the asserted knowledge should be saved in standard or convertible formats for use by different communities; 3) The interface should be simple to users with customizable options and views.

Usability testing. A major activity of iProLINK will be to facilitate interactions between text mining and user communities through annual workshops including joint workshops with existing activities, such as BioCreative and International BioCuration Meetings. An annotation workshop will allow database curators to experiment with integrating multiple text mining tools into their workflow. This will provide an opportunity for investigation of usability testing, a widely neglected topic in literature text mining. Building on the coauthors' extensive experience in evaluation of interactive systems [30], we will employ well-understood formal and informal techniques for user interface evaluation—those specific to search interfaces [31] or in general [32]—to address the lack of research into user interface design for biomedical text mining tools for curators.

5. Conclusion

We have presented a basic framework, iProLINK, to link the text mining tool developers to the ontology and systems biology user/curator communities. We used several use cases to illustrate the need and feasibility of bridging disparate communities, and analyzed requirements of the interface and major gaps in the community effort. A well designed interface and community workshops for curation and evaluation of tools will be the keys for success.

Text Mining for Database Curation

Organizer: Cathy H. Wu, Georgetown University Medical Center (wuc@georgetown.edu)

ABSTRACT

repository of biological knowledge. The The biological literature represents the increasing volume of scientific literature now available electronically and the exponential growth of large-s cale molecular d at have p rompted active research in biolog ical text mining to fa cilitate literature-based database curation. In particular, evidence attribution of experimentally validated inform ation extr acted f rom the sc ientific litera ture will become increasingly important to ensure the annotation quality of biological databases. Many text mining tools and resources have been developed. There are community efforts, such as the BioCreativ e Challenge Evaluations, for evaluating text m applied to the biological domain. However, these tools are still not being fully utilized by the broad biological user communities. Such a gap is partly due to intrinsic complexity of biological text for mining, and partly to the l ack of data standards and close interactions between the text m ining and user comm unities to conduct utility /usability analysis and use case development. This workshop will include presentations and a panel discussion to facilitate the developm ent of text m ining system s that address the needs of the biocuration and biological research community.

SPEAKERS

8:00-8:10 am Cathy Wu

Introduction

8:10-8:40 am Carl Schmidt

Text-Mining to Aid Annotation of the Gallus Reactome

8:40-9:10 am Lynette Hirschman

BioCreative: Evaluating Text Mining for the BioCuration Workflow

9:10-9:40 am Cathy Wu

iProLINK: Linking Text Mining with Ontology and Systems Biology

9:40-10:10 am Panel discussion

Text Mining for Database Curation

Text-Mining to Aid Annotation of the Gallus Reactome

<u>Carl J. Schmidt</u>¹, Catalina Oana Tudor¹, Li Jin, Keith Decker¹, Peter D'Eustachio², and Vijay Shanker¹

¹University of Delaware, ² New York University, School of Medicine schmidtc@udel.edu, oanat@UDel.Edu, jin@mail.eecis.udel.edu, decker@cis.udel.edu, Peter.D'Eustachio@nyumc.org, vijay@cis.udel.edu

The objective of Gallus Reactome is to provide a curated set of metabolic and signaling pathways for the chicken. To assist annotators, we are developing a set of tools designed to extract and prioritize text from abstracts that are relevant to the gene products being annotated. Key terms extracted from abstracts with eGIFT are grouped by whether the key term describes the target gene product alone or describes its interaction with other proteins. The latter group is likely to be of greater importance to Reactome annotators. Since Gallus Reactome is particularly interested in papers that document pathways in the chicken, abstracts are classified according to the species that were the source of the experimental material. The annotator is provided with a web page containing sentences that have been prioritized according to the species of interest, and the likelihood that the sentences are relevant to pathways. The annotator can choose to view the complete abstract or article containing sentences that appear relevant to the current task. Sentences can also be saved to a GeneWiki page that allows the scientific community rapid access to information the annotator viewed as germane to the reaction pathway.

BioCreative: Evaluating Text Mining for the BioCuration Workflow

Lynette Hirschman
The MITRE Corporation
lynette@mitre.org

There has been increasing interest in applying text mining technology to BioCuration, but it is still difficult to point to major successful applications, or to determine what tools are available for which aspects of curation. BioCreative (Critical Assessment of Information Extraction in Biology) was organized to encourage progress in this important area through development of Challenge Evaluations, focused largely on the biocuration workflow – see the recent special issue of Genome Biology (Vol 9, Suppl 2 2008). In BioCreative II, the curators from the MINT and IntAct protein-protein interaction databases provided a "gold standard" expert curated data set against which to compare performance of text mining tools. This advanced task, developed by Martin Krallinger in Alfonso Valencia's group at CNIO, included identification of relevant articles for curation, extraction of interacting proteins (with their SwissProt identifiers), extraction of experimental methods, and identification of supporting textual evidence. In a first step towards making these tools available, many of the participants in BioCreative II have contributed their tools to a MetaServer (http://bcms.bioinfo.cnio.es/), developed by the team at the CNIO. For BioCreative III, working with Cathy Wu and the PIR curation

team, our goal is to assess text mining tools "in situ" – for example, in the context of a curation jamboree, with curators providing an evaluation of the usability and utility of the tools. BioCreative III is planned for 2009-2010, and we are soliciting input, requirements and participation from the BioCurator community.

*This work is supported by NSF Grant IIS-0844419.

iProLINK: Linking Text Mining with Ontology and Systems Biology

Cathy H. Wu Georgetown University Medical Center wuc@georgetown.edu

The rapid growth of scientific literature a nd of large-s cale molecular data has prompte d active research in bio logical text m ining to facilitate literature-based database curation. Meanwhile, system's biology knowledgebases a nd ontologies are em erging as critica 1 tools in bio logical research where com plex data in disp arate resources need to integrated and annotated. PIR has develope diProLINK as a resource to support text mining research. It p rovides literature co rpora with annotation-tagged abstracts for training and benchm arking text mining tools, as well as tools such as RLIMS-P for mining protein phosphorylation objects from MEDLINE abstracts and BioThesaurus for identification of synonymous and ambiguous gene/protein names to support named entity recognition. Built on iP roLINK, PIR is deve loping a fram ework for linking text mining with ontology and system's biology, focusing on integration of public text m ining tools for mining protein-protein interactions, including the post-translational modifications and pathogen-host interactions. Use cases will be presented with applications for curation of molecular and ontological data and analysis of systems biology data in the network and pathway co ntext. The f ramework will f acilitate the u tility, usability a nd requirement analyses by biologists to guide future development of text mining tools and systems that will be broadly utilized by biologists for database curation and knowledge discovery.
